Abstract

In this note we point out that the limit shape of Jarník's polygonal curve [**1**] is the circle, not a curve consisting of arcs of parabolas as it has been stated in the main result of [**2**] (Section 2). The correct result has been established and proven in [**4**].

1. *Introduction*

In order to establish the maximum number $f(s)$ of lattice points on a strictly convex curve of length at most s, Jarník [**1**] has considered a family of convex lattice polygons. Vertices of these polygons lie on strictly convex curves which optimize $f(s)$, in an asymptotic sense. It has been shown [**4**] that there is a limit shape of such polygons. More precisely, as the number of vertices of these polygons increase and after a proper scaling (e.g., for a factor equal to the perimeter of the related polygon) these polygons converge to a circle. The result has been derived starting from the family of the convex lattice polygons whose edge slopes q/a belong to the set V_t, defined as follows (for an arbitrary $t > 1$):

$$V_t = \left\{ (q,a) \in \mathbf{Z}^2 \ : \ \gcd(q,a) = 1; \ \ \sqrt{q^2+a^2} \le t \right\}. \tag{1.1}$$

Another family of convex lattice polygons has been considered in [**2**]. The edge slopes q/a of lattice polygons from this family make the set V_Q, defined for all $Q > 1$, as follows

$$V_Q = \left\{ (q,a) \in \mathbf{Z}^2 \ : \ \gcd(q,a) = 1; \ \ \max\{|a|,|q|\} \le Q \right\}. \tag{1.2}$$

The polygons V_Q do not relate to the Jarník's polygons (i.e., do not optimize the number of the polygon vertices with respect to the Euclidean perimeter of the polygon), as it has been stated in [**2**]. Indeed, the observation of V_Q, as given in [**2**], does not lead to a conclusion about the number of lattice points on a strictly convex curve with respect to the Euclidean length of this curve.

Thus, the statement, from [**2**], that the limiting curve of Jarník's polygons consist of parabolic arcs is not true. The limit shape of such polygons is a circle, as it has been shown in [**4**]. The result from [**2**] can be considered in sense of the maximal number of lattice points, on a strictly convex curve, with respect to the curve perimeter taken in sense of l_∞ distance, rather than in sense of the l_2 (i.e. Euclidean) distance.

It is also worth mentioning the following: The some of the results from [**2**] (see Section 2) are derived following the idea and technique from [**4**] and [**5**], but this was not referenced properly; The term 'limit shape' has been used by the others (see [**3**], for an example) but in different sense than it has been done in [**2**], [**4**], and [**5**].
